

# *Hedging Issues for CDOs*

*Credit Risk Summit*

*London*

*8 June 2007*

*Jean-Paul LAURENT*

*Professor, ISFA Actuarial School, University of Lyon,*

*Scientific consultant, BNP PARIBAS*

<http://laurent.jeanpaul.free.fr>

**Presentation related to papers**

**A note on the risk management of CDOs (2006)**

**Hedging default risks of CDOs in Markovian contagion models (2007)**

**Available on [www.defaultrisk.com](http://www.defaultrisk.com)**

## *Hedging Default and Credit Spread Risks within CDOs*

- Purpose of the presentation
  - Not trying to embrace all risk management issues
  - Focus on very specific aspects of default and credit spread risk
- Overlook of the presentation
  - Economic background
  - Tree approach to hedging defaults
  - Hedging credit spread risks for large portfolios

## *I - Economic Background*

- Hedging CDOs context
- About 1 000 papers on defaultrisk.com
- About 10 papers dedicated to hedging issues
  - **In interest rate or equity markets, pricing is related to the cost of the hedge**
  - **In credit markets, pricing is disconnect from hedging**
- Need to relate pricing and hedging
- What is the business model for CDOs?
- Risk management paradigms
  - Static hedging, risk-return arbitrage, complete markets

## *I - Economic Background*

- Static hedging
- Buy a portfolio of credits, split it into tranches and sell the tranches to investors
  - No correlation or model risk for market makers
  - No need to dynamically hedge with CDS
- Only « budget constraint »:
  - Sum of the tranche prices greater than portfolio of credits price
  - Similar to stripping ideas for Treasury bonds
- No clear idea of relative value of tranches
  - Depends of demand from investors
  - Markets for tranches might be segmented

## *I - Economic Background*

- Risk – return arbitrage
- Historical returns are related to ratings, factor exposure
  - CAPM, equilibrium models
  - **In search of high alphas**
  - **Relative value deals, cross-selling along the capital structure**
- Depends on the presence of « arbitrageurs »
  - Investors with small risk aversion
    - Trading floors, hedge funds
  - Investors without too much accounting, regulatory, rating constraints

## *I - Economic Background*

- The ultimate step : complete markets
  - As many risks as hedging instruments
  - News products are only designed to save transactions costs and are used for risk management purposes
  - Assumes a high liquidity of the market
- Perfect replication of payoffs by dynamically trading a small number of « underlying assets »
  - Black-Scholes type framework
  - Possibly some model risk
- This is further investigated in the presentation
  - Dynamic trading of CDS to replicate CDO tranche payoffs

## *I - Economic Background*

- Default risk
  - Default bond price jumps to recovery value at default time.
  - Drives the CDO cash-flows
- Credit spread risk
  - Changes in defaultable bond prices prior to default
    - Due to shifts in credit quality or in risk premiums
  - Changes in the marked to market of tranches
- Interactions between credit spread and default risks
  - Increase of credit spreads increase the probability of future defaults
  - Arrival of defaults may lead to jump in credit spreads
    - Contagion effects (Jarrow & Yu)

## *I - Economic Background*

- Credit deltas in copula models
- CDS hedge ratios are computed by bumping the marginal credit curves
  - Local sensitivity analysis
  - Focus on credit spread risk
  - Deltas are copula dependent
  - Hedge over short term horizons
    - Poor understanding of gamma, theta, vega effects
    - Does not lead to a replication of CDO tranche payoffs
- Last but not least: not a hedge against defaults...

# I - Economic Background

- Credit deltas in copula models
  - Stochastic correlation model (Burstschell, Gregory & Laurent, 2007)

## *II - Tree approach to hedging defaults*

- Main assumptions and results
  - Credit spreads are driven by defaults
    - Contagion model
    - Credit spreads are deterministic between two defaults
  - Homogeneous portfolio
    - Only need of the CDS index
    - No individual name effect
  - Markovian dynamics
    - Pricing and hedging CDOs within a binomial tree
    - Easy computation of dynamic hedging strategies
    - Perfect replication of CDO tranches

## *II - Tree approach to hedging defaults*

- We will start with two names only
- Firstly in a static framework
  - Look for a First to Default Swap
  - Discuss historical and risk-neutral probabilities
- Further extending the model to a dynamic framework
  - Computation of prices and hedging strategies along the tree
  - Pricing and hedging of tranchelets
- Multiname case: homogeneous Markovian model
  - Computation of risk-neutral tree for the loss
  - Computation of dynamic deltas
- Technical details can be found in the paper:
  - “hedging default risks of CDOs in Markovian contagion models”

## II - Tree approach to hedging defaults

- Some notations :
  - $\tau_1, \tau_2$  default times of counterparties 1 and 2,
  - $\mathcal{H}_t$  available information at time  $t$ ,
  - $P$  historical probability,
  - $\alpha_1^P, \alpha_2^P$  : (historical) default intensities:
    - $P[\tau_i \in [t, t + dt] | \mathcal{H}_t] = \alpha_i^P dt, i = 1, 2$
- Assumption of « local » independence between default events
  - Probability of 1 and 2 defaulting altogether:
    - $P[\tau_1 \in [t, t + dt], \tau_2 \in [t, t + dt] | \mathcal{H}_t] = \alpha_1^P dt \times \alpha_2^P dt$  in  $(dt)^2$
  - Local independence: simultaneous joint defaults can be neglected

## II - Tree approach to hedging defaults

- Building up a tree:
  - Four possible states:  $(D,D)$ ,  $(D,ND)$ ,  $(ND,D)$ ,  $(ND,ND)$
  - Under no simultaneous defaults assumption  $p_{(D,D)}=0$
  - Only three possible states:  $(D,ND)$ ,  $(ND,D)$ ,  $(ND,ND)$
  - Identifying (historical) tree probabilities:

$$\begin{cases} p_{(D,D)} = 0 \Rightarrow p_{(D,ND)} = p_{(D,D)} + p_{(D,ND)} = p_{(D,\cdot)} = \alpha_1^P dt \\ p_{(D,D)} = 0 \Rightarrow p_{(ND,D)} = p_{(D,D)} + p_{(ND,D)} = p_{(\cdot,D)} = \alpha_2^P dt \\ p_{(ND,ND)} = 1 - p_{(D,\cdot)} - p_{(\cdot,D)} \end{cases}$$

## II - Tree approach to hedging defaults

- Stylized cash flows of short term digital CDS on counterparty 1:

–  $\alpha_1^Q dt$  CDS 1 premium

- Stylized cash flows of short term digital CDS on counterparty 2:

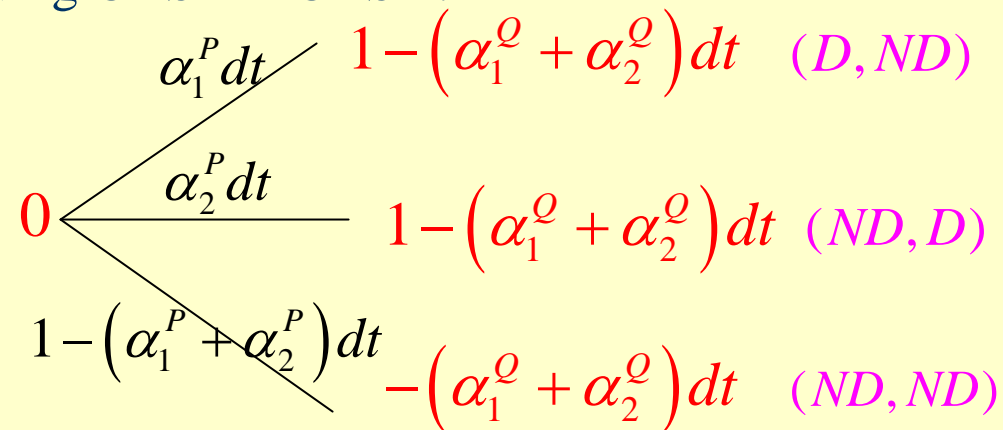

## II - Tree approach to hedging defaults

- Cash flows of short term digital first to default swap with premium  $\alpha_F^Q dt$  :

- Cash flows of holding CDS 1 + CDS 2:

- Perfect hedge of first to default swap by holding 1 CDS 1 + 1 CDS 2
  - Delta with respect to CDS 1 = 1, delta with respect to CDS 2 = 1

## II - Tree approach to hedging defaults

- Absence of arbitrage opportunities imply:
  - $\alpha_F^Q = \alpha_1^Q + \alpha_2^Q$
- Arbitrage free first to default swap premium
  - Does not depend on historical probabilities  $\alpha_1^P, \alpha_2^P$
- Three possible states:  $(D, ND)$ ,  $(ND, D)$ ,  $(ND, ND)$
- Three tradable assets: CDS1, CDS2, risk-free asset

- For simplicity, let us assume  $r = 0$

## II - Tree approach to hedging defaults

- Three state contingent claims

- Example: claim contingent on state  $(D, ND)$
- Can be replicated by holding
- 1 CDS  $1 + \alpha_1^Q dt$  risk-free asset

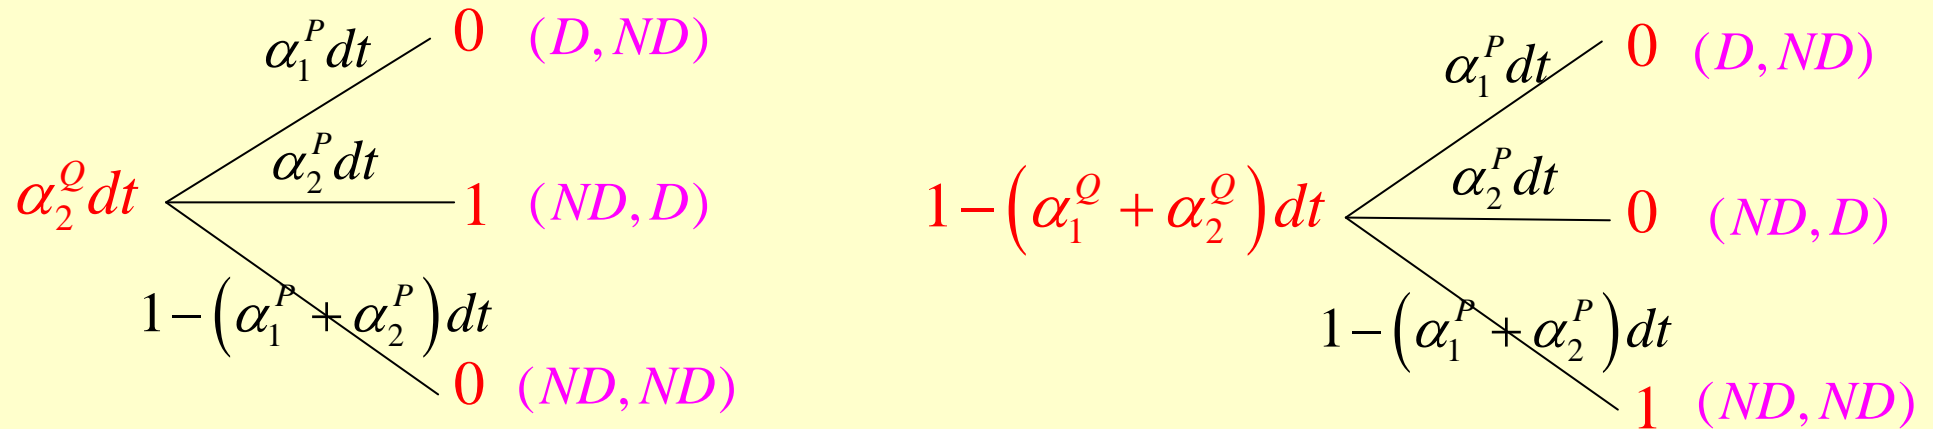

- Replication price =  $\alpha_1^Q dt$

## II - Tree approach to hedging defaults

- Similarly, the replication prices of the  $(ND, D)$  and  $(ND, ND)$  claims

- Replication price of:

- Replication price =  $\alpha_1^Q dt \times a + \alpha_2^Q dt \times b + (1 - (\alpha_1^Q + \alpha_2^Q) dt) c$

## II - Tree approach to hedging defaults

- Replication price obtained by computing the expected payoff
  - Along a risk-neutral tree

$$\alpha_1^Q dt \times a + \alpha_2^Q dt \times b + \left(1 - (\alpha_1^Q + \alpha_2^Q) dt\right) c$$

$\alpha_1^Q dt$   $a$   $(D, ND)$   
 $\alpha_2^Q dt$   $b$   $(ND, D)$   
 $1 - (\alpha_1^Q + \alpha_2^Q) dt$   $c$   $(ND, ND)$

- Risk-neutral probabilities
  - Used for computing replication prices
  - Uniquely determined from short term CDS premiums
  - No need of historical default probabilities

## II - Tree approach to hedging defaults

- Computation of deltas

- Delta with respect to CDS 1:  $\delta_1$
- Delta with respect to CDS 2:  $\delta_2$
- Delta with respect to risk-free asset:  $p$ 
  - $p$  also equal to up-front premium

$$\left\{ \begin{array}{l} a = p + \delta_1 \times \overbrace{\left(1 - \alpha_1^Q dt\right)}^{\text{payoff CDS 1}} + \delta_2 \times \overbrace{\left(-\alpha_2^Q dt\right)}^{\text{payoff CDS 2}} \\ b = p + \delta_1 \times \left(-\alpha_1^Q dt\right) + \delta_2 \times \left(1 - \alpha_2^Q dt\right) \\ c = p + \underbrace{\delta_1 \times \left(-\alpha_1^Q dt\right)}_{\text{payoff CDS 1}} + \underbrace{\delta_2 \times \left(-\alpha_2^Q dt\right)}_{\text{payoff CDS 2}} \end{array} \right.$$

- As for the replication price, deltas only depend upon CDS premiums

## II - Tree approach to hedging defaults

- Dynamic case:

- $\lambda_2^O dt$  CDS 2 premium after default of name 1
- $\kappa_1^O dt$  CDS 1 premium after default of name 2
- $\pi_1^O dt$  CDS 1 premium if no name defaults at period 1
- $\pi_2^O dt$  CDS 2 premium if no name defaults at period 1
- Change in CDS premiums due to contagion effects
  - Usually,  $\pi_1^O < \alpha_1^O < \lambda_1^O$  and  $\pi_2^O < \alpha_2^O < \lambda_2^O$

## *II - Tree approach to hedging defaults*

- Computation of prices and hedging strategies by backward induction
  - use of the dynamic risk-neutral tree
  - Start from period 2, compute price at period 1 for the three possible nodes
  - + hedge ratios in short term CDS 1,2 at period 1
  - Compute price and hedge ratio in short term CDS 1,2 at time 0
- Example to be detailed:
  - computation of CDS 1 premium, maturity = 2
  - $p_1 dt$  will denote the periodic premium
  - Cash-flow along the nodes of the tree

## II - Tree approach to hedging defaults

- Premium of CDS on name 1, maturity = 2, time = 0,  $p_1 dt$  solves for:

$$\begin{aligned}
 0 = & (1 - p_1) \alpha_1^0 + \left( -p_1 + (1 - p_1) \kappa_1^0 - p_1 (1 - \kappa_1^0) \right) \alpha_2^0 \\
 & + \left( -p_1 + (1 - p_1) \pi_1^0 - p_1 \pi_2^0 - p_1 (1 - \pi_1^0 - \pi_2^0) \right) (1 - \alpha_1^0 - \alpha_2^0)
 \end{aligned}$$

## II - Tree approach to hedging defaults

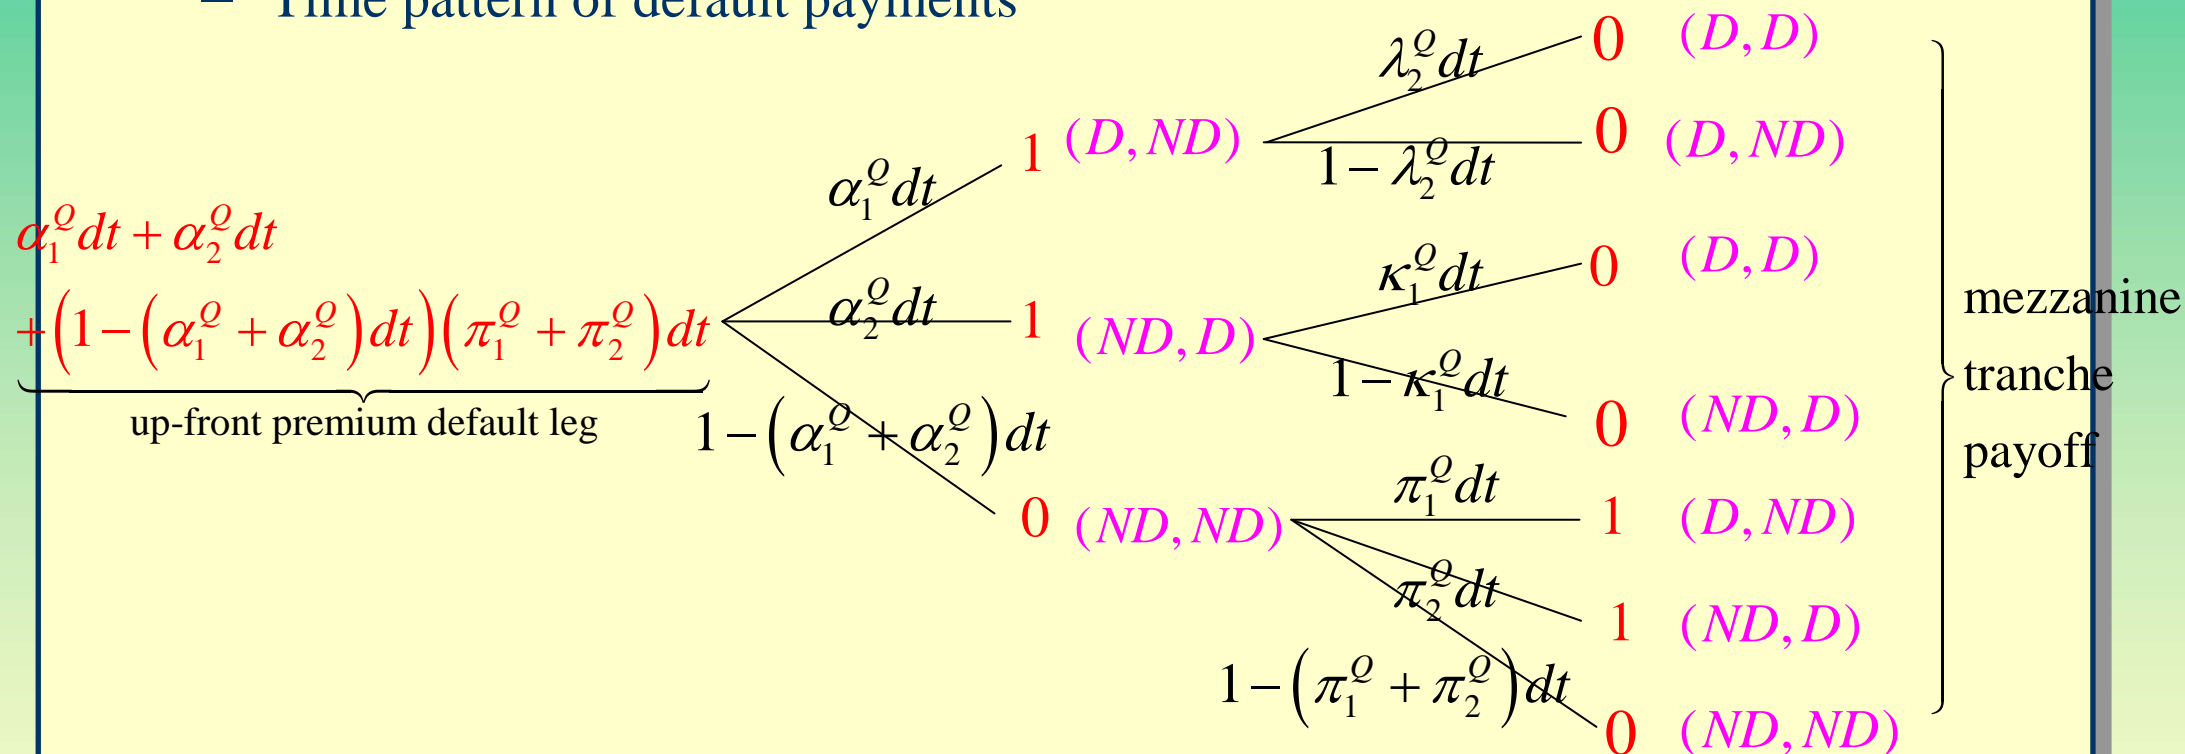

- Example: stylized zero coupon CDO tranchelets
  - Zero-recovery, maturity 2
  - Aggregate loss at time 2 can be equal to 0,1,2
    - Equity type tranche contingent on no defaults
    - Mezzanine type tranche : one default
    - Senior type tranche : two defaults

## II - Tree approach to hedging defaults

- mezzanine tranche
  - Time pattern of default payments

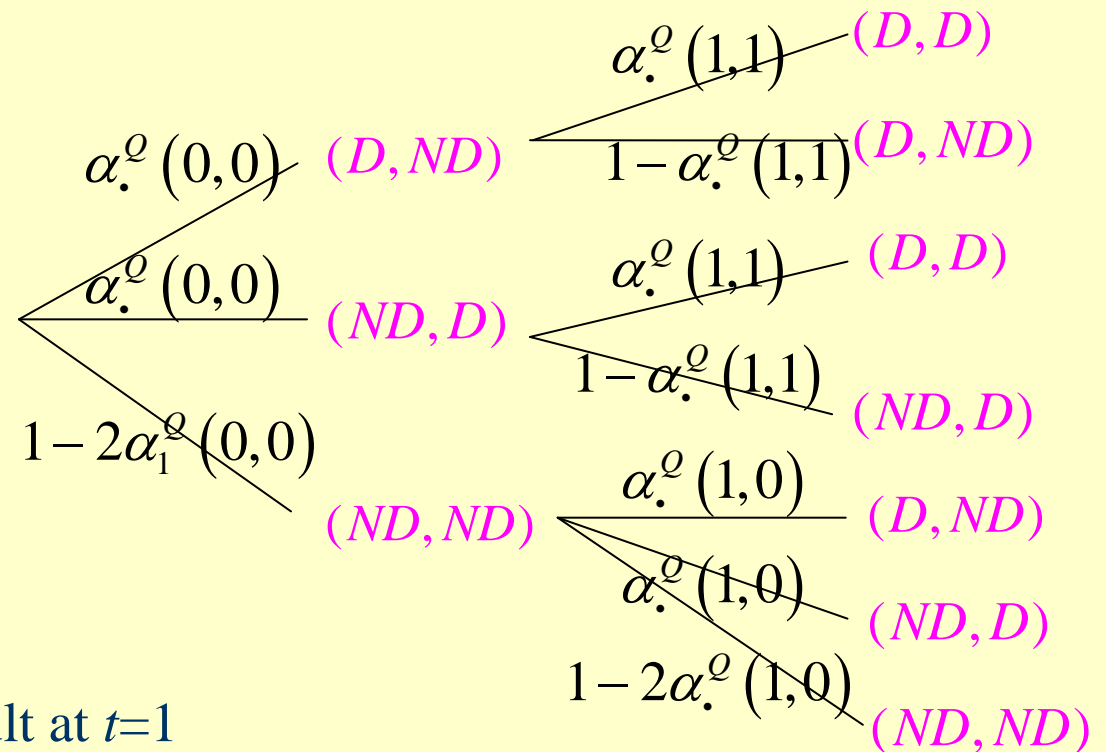

- Possibility of taking into account discounting effects
- The timing of premium payments
- Computation of dynamic deltas with respect to short or actual CDS on names 1,2

## *II - Tree approach to hedging defaults*

- In theory, one could also derive dynamic hedging strategies for index CDO tranches
  - Numerical issues: large dimensional, non recombining trees
  - Homogeneous Markovian assumption is very convenient
    - CDS premiums at a given time  $t$  only depend upon the current number of defaults  $N(t)$
  - CDS premium at time 0 (no defaults)  $\alpha_1^Q dt = \alpha_2^Q dt = \alpha^Q (t = 0, N(0) = 0)$
  - CDS premium at time 1 (one default)  $\lambda_2^Q dt = \kappa_1^Q dt = \alpha^Q (t = 1, N(t) = 1)$
  - CDS premium at time 1 (no defaults)  $\pi_1^Q dt = \pi_2^Q dt = \alpha^Q (t = 1, N(t) = 0)$

## II - Tree approach to hedging defaults

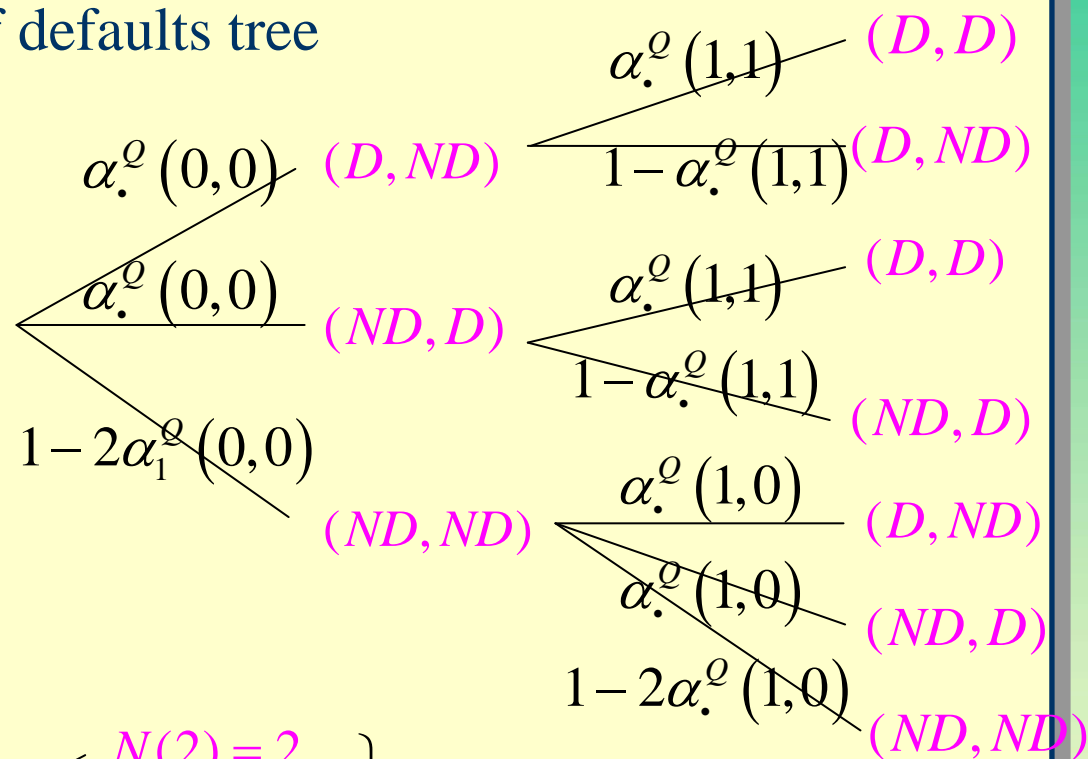

- Homogeneous Markovian tree

- If we have  $N(1) = 1$ , one default at  $t=1$
- The probability to have  $N(2) = 1$ , one default at  $t=2$ ...
- Is  $1 - \alpha^Q(1,1)$  and does not depend on the defaulted name at  $t=1$
- $N(t)$  is a Markov process
- Dynamics of the number of defaults can be expressed through a binomial tree

## II - Tree approach to hedging defaults

- From name per name to number of defaults tree

## II - Tree approach to hedging defaults

- Easy extension to  $n$  names

- Predefault name intensity at time  $t$  for  $N(t)$  defaults:  $\alpha_{\cdot}^{\varrho}(t, N(t))$

- Number of defaults intensity : sum of surviving name intensities:

$$\lambda(t, N(t)) = (n - N(t)) \alpha_{\cdot}^{\varrho}(t, N(t))$$

- $\alpha_{\cdot}^{\varrho}(0,0), \alpha_{\cdot}^{\varrho}(1,0), \alpha_{\cdot}^{\varrho}(1,1), \alpha_{\cdot}^{\varrho}(2,0), \alpha_{\cdot}^{\varrho}(2,1), \dots$  can be easily calibrated

- on marginal distributions of  $N(t)$  by forward induction.

## II - Tree approach to hedging defaults

- Previous recombining binomial risk-neutral tree provides a framework for the valuation of payoffs depending upon the number of defaults

- CDO tranches
- Credit default swap index

- What about the credit deltas?

- In a homogeneous framework, deltas with respect to CDS are all the same
- Perfect dynamic replication of a CDO tranche with a credit default swap index and the default-free asset
- Credit delta with respect to the credit default swap index
- = change in PV of the tranche / change in PV of the CDS index

## *II - Tree approach to hedging defaults*

- Example: number of defaults distribution at 5Y generated from a Gaussian copula

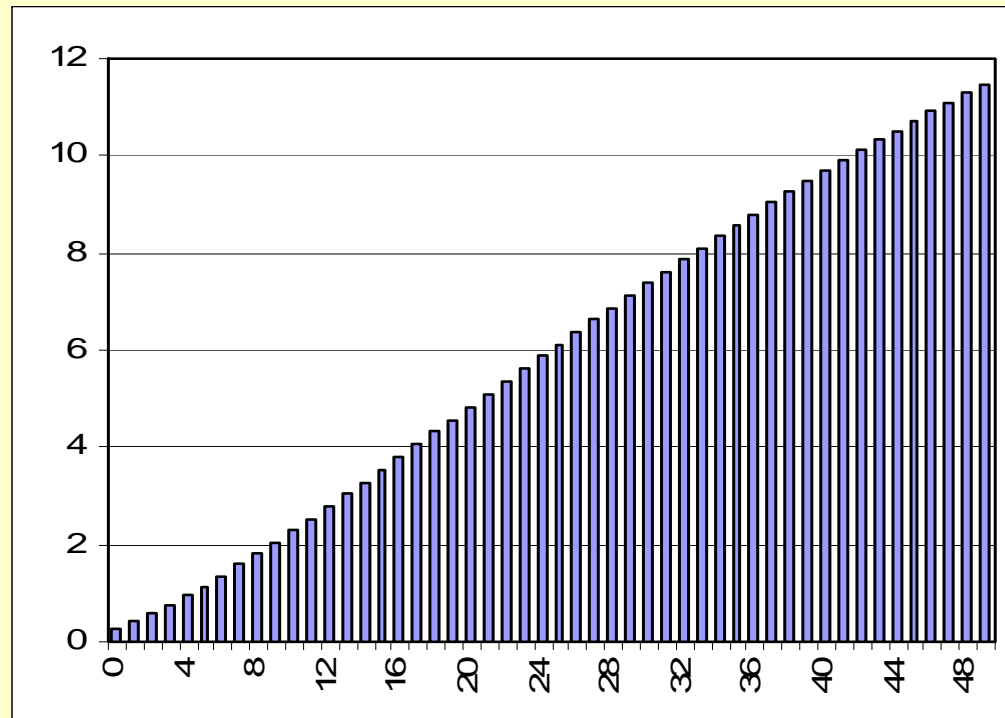

- Correlation parameter: 30%
- Number of names: 125
- Default-free rate: 3%
- 5Y credit spreads: 20 bps
- Recovery rate: 40%

- Figure shows the corresponding expected losses for a 5Y horizon

## *II - Tree approach to hedging defaults*

- Calibration of loss intensities
  - For simplicity, assumption of time homogeneous intensities
  - Figure below represents loss intensities, with respect to the number of defaults
  - Increase in intensities: contagion effects

## II - Tree approach to hedging defaults

- Dynamics of the 5Y CDS index spread
  - In bp pa

	7	0.00%	0	0	0	0	0	0	0

- **Credit deltas of the premium leg of the equity tranche**
  - **Premiums based on outstanding nominal**
  - **Arrival of defaults reduces the commitment to pay**
    - **Smaller outstanding nominal**
    - **Increase in credit spreads (contagion) involve a decrease in expected outstanding nominal**
  - **Negative deltas**
    - **This is only significant for the equity tranche**
      - **Associated with much larger spreads**

## II - Tree approach to hedging defaults

		OutStanding Nominal	Weeks						
			0	14	28	42	56	70	84
Nb Defaults	0	3.00%	0.814	0.843	0.869	0.893	0.915	0.933	0.949
	1	2.52%	0	0.614	0.658	0.702	0.746	0.787	0.827
	2	2.04%	0	0.341	0.384	0.431	0.482	0.535	0.591
	3	1.56%	0	0.140	0.165	0.194	0.229	0.269	0.315
	4	1.08%	0	0.045	0.054	0.064	0.078	0.095	0.117
	5	0.60%	0	0.013	0.015	0.017	0.020	0.024	0.030

	7	0.00%	0	0	0	0	0	0	0

- **Credit deltas for the default leg of the equity tranche**
  - Are actually between 0 and 1
  - Gradually decrease with the number of defaults
    - Concave payoff, negative gammas
  - Credit deltas increase with time
    - Consistent with a decrease in time value
    - At maturity date, when number of defaults < 6, delta=1

## II - Tree approach to hedging defaults

- Dynamics of credit deltas
  - Junior mezzanine tranche [3,6%]
  - Deltas lie in between 0 and 1
  - When the number of defaults is above 12, the tranche is exhausted

		OutStanding Nominal	Weeks

## II - Tree approach to hedging defaults

- **Comparison analysis**
  - After six defaults, the [3,6%] should be like a [0,3%] equity tranche
  - However, credit delta is much lower
    - 12% instead of 84%
  - But credit spreads after six defaults are much larger
    - 127 bps instead of 19 bps
  - Expected loss of the tranche is much larger
  - Which is associated with smaller deltas

## II - Tree approach to hedging defaults

$$\left\{ \begin{array}{l} \rho = 10\%, N(14) = 0, \delta = 97\% \\ \rho = 30\%, N(14) = 0, \delta = 84\% \end{array} \right. \quad \left\{ \begin{array}{l} \rho = 10\%, N(14) = 1, \delta = 93\% \\ \rho = 30\%, N(14) = 1, \delta = 61\% \end{array} \right.$$

- Smaller correlation
  - Prior to first default, higher expected losses on the tranche
    - Should lead to smaller deltas
  - But smaller contagion effects
    - When shifting from zero to one default
    - The expected loss on the index jumps due to...
      - **Default arrival and jumps in credit spreads**
      - **Smaller jumps in credit spreads for smaller correlation**
    - Smaller correlation is associated with smaller jumps in the expected loss of the index
    - Leads to higher deltas
      - **Since we have negative gamma**

## *II - Tree approach to hedging defaults*

- What do we learn from this hedging approach?
  - Thanks to stringent assumptions:
    - **credit spreads driven by defaults**
    - **homogeneity**
    - **Markov property**
  - It is possible to compute a dynamic hedging strategy
    - **Based on the CDS index**
  - That fully replicates the CDO tranche payoffs
    - **Model matches market quotes of liquid tranches**
    - **Very simple implementation**
    - **Credit deltas are easy to understand**
  - Improve the computation of default hedges
    - **Since it takes into account credit contagion**
  - Credit spread dynamics needs to be improved

### *III - Hedging credit spread risks for large portfolios*

- When dealing with the risk management of CDOs, traders
  - concentrate upon credit spread and correlation risk
  - Neglect default risk
- What about default risk ?
  - For large indices, default of one name has only a small direct effect on the aggregate loss
- Is it possible to build a framework where hedging default risk can be neglected?
- And where one could only consider the hedging of credit spread risk?
  - See paper “A Note on the risk management of CDOs”

### III - Hedging credit spread risks for large portfolios

- Main and critical assumption
  - Default times follow a multivariate Cox process
    - For instance, affine intensities
    - Duffie & Garleanu, Mortensen, Feldhütter, Merrill Lynch

2. the default times follow a multivariate Cox process:

$$\tau_i = \inf \left\{ t \in \mathbb{R}^+, U_i \geq \exp \left( - \int_0^t \lambda_{i,u} du \right) \right\}, \quad i = 1, \dots, n \quad (2.2)$$

where  $\lambda_1, \dots, \lambda_n$  are strictly positive,  $\mathcal{F}$  - progressively measurable processes,  $U_1, \dots, U_n$  are independent random variables uniformly distributed on  $[0, 1]$  under  $Q$  and  $\mathcal{F}$  and  $\sigma(U_1, \dots, U_n)$  are independent under  $Q$ .

- No contagion effects

### *III - Hedging credit spread risks for large portfolios*

- No contagion effects
  - credit spreads drive defaults but defaults do not drive credit spreads
  - For a large portfolio, default risk is perfectly diversified
  - Only remains credit spread risks: parallel & idiosyncratic
- Main result
  - With respect to dynamic hedging, default risk can be neglected
  - Only need to focus on dynamic hedging of credit spread risks
    - With CDS
  - Similar to interest rate derivatives markets

### III - Hedging credit spread risks for large portfolios

- Formal setup
  - $\tau_1, \dots, \tau_n$  default times
  - $N_i(t) = 1_{\{\tau_i \leq t\}}, i = 1, \dots, n$  default indicators
  - $H_t = \bigvee_{i=1, \dots, n} \sigma(N_i(s), s \leq t)$  natural filtration of default times
  - $F_t$  background (credit spread filtration)
  - $G_t = H_t \vee F_t$  enlarged filtration,  $P$  historical measure
  - $l_i(t, T), i = 1, \dots, n$  time  $t$  price of an asset paying  $N_i(T)$  at time  $T$

### III - Hedging credit spread risks for large portfolios

- Sketch of the proof
- Step 1: consider some smooth shadow risky bonds
  - Only subject to credit spread risk
  - Do not jump at default times
- Projection of the risky bond prices on the credit spread filtration

**Definition 3.2** *The default free  $T$  forward loss process associated with name  $i \in \{0, \dots, n\}$ , denoted by  $p^i(\cdot, T)$  is such that for  $0 \leq t \leq T$ :*

$$p^i(t, T) \triangleq E^Q [p^i(T) | \mathcal{F}_t] = E^Q [N_i(T) | \mathcal{F}_t] = Q(\tau_i \leq T | \mathcal{F}_t). \quad (3.2)$$

**Lemma 3.1**  *$p^i(t, T)$ ,  $i = 1, \dots, n$  are projections of the forward price processes  $l^i(t, T)$  on  $\mathcal{F}_t$ :*

$$p^i(t, T) = E^Q [l^i(t, T) | \mathcal{F}_t], \quad (3.3)$$

*for  $i = 1, \dots, n$  and  $0 \leq t \leq T$ .*

### III - Hedging credit spread risks for large portfolios

- Step 2: Smooth the aggregate loss process
- ... and thus the tranche payoffs
  - Remove default risk and only consider credit spread risk
  - Projection of aggregate loss on credit spread filtration

**Definition 3.1** We denote by  $p^i(\cdot)$ , the **default-free running loss process** associated with name  $i \in \{0, \dots, n\}$ , which is such that for  $0 \leq t \leq T$ :

$$p^i(t) \triangleq E^Q[N_i(t) \mid \mathcal{F}_t] = Q(\tau_i \leq t \mid \mathcal{F}_t) = 1 - \exp(-\Lambda_{i,t}). \quad (3.1)$$

**Definition 3.5 default-free aggregate running loss process** The default free aggregate running loss at time  $t$  is such that for  $0 \leq t \leq T$ :

$$p_n(t) \triangleq \frac{1}{n} \sum_{i=1}^n p^i(t). \quad (3.7)$$

### III - Hedging credit spread risks for large portfolios

- Step 3: compute perfect hedge ratios of the smoothed payoff
  - With respect to the smoothed risky bonds
    - Smoothed payoff and risky bonds only depend upon credit spread dynamics
    - Both idiosyncratic and parallel credit spread risks
    - Similar to a multivariate interest rate framework
    - Perfect hedging in the smooth market

**Assumption 2** *There exists some bounded  $\mathcal{F}$  - predictable processes  $\theta_1(\cdot), \dots, \theta_n(\cdot)$  such that:*

$$(p_n(T) - K)^+ = E^Q [(p_n(T) - K)^+] + \frac{1}{n} \sum_{i=1}^n \int_0^T \theta_i(t) dp^i(t, T) + z_n, \quad (4.2)$$

*where  $z_n$  is  $\mathcal{F}_T$ -measurable, of  $Q$ -mean zero and  $Q$ -strongly orthogonal to  $p^1(\cdot, T), \dots, p^n(\cdot, T)$ .*

### III - Hedging credit spread risks for large portfolios

- Step 4: apply the hedging strategy to the true defaultable bonds
- **Main result**
  - Bound on the hedging error following the previous hedging strategy
  - When hedging an actual CDO tranche with actual defaultable bonds
  - Hedging error decreases with the number of names

#### ➤ Default risk diversification

**Proposition 1** Under Assumptions (1) and (2), the hedging error  $\varepsilon_n$  defined as:

$$\varepsilon_n = (l_n(T) - K)^+ - E^Q [(l_n(T) - K)^+] - \frac{1}{n} \sum_{i=1}^n \int_0^T \theta_i(t) dl^i(t, T), \quad (4.4)$$

is such that  $E^P[|\varepsilon_n|]$  is bounded by:

$$\frac{1}{\sqrt{2n}} \left( 1 + \left( E^Q \left[ \left( \frac{dP}{dQ} \right)^2 \right] \right)^{1/2} \right) + \frac{1}{n} \left( E^Q \left[ \left( \frac{dP}{dQ} \right)^2 \right] \right)^{1/2} \left( \sum_{i=1}^n (Q(\tau_i \leq T) + E^Q [B_i|_T]) \right)^{1/2} + E^P[|z_n|]. \quad (4.5)$$

### *III - Hedging credit spread risks for large portfolios*

- Provides a hedging technique for CDO tranches
  - Known theoretical properties
  - Takes into account idiosyncratic and parallel gamma risks
  - Good theoretical properties rely on no simultaneous defaults, no contagion effects assumptions
  - Empirical work remains to be done
- Thought provocative
  - To construct a practical hedging strategy, do not forget default risk
  - Equity tranche [0,3%]
  - iTraxx or CDX first losses cannot be considered as smooth

## *Hedging credit spread risk for large portfolios*

- Linking pricing and hedging ?
- The black hole in CDO modeling ?
- Standard valuation approach in derivatives markets
  - Complete markets
  - Price = cost of the hedging/replicating portfolio
- Mixing of dynamic hedging strategies
  - for credit spread risk
- And diversification/insurance techniques
  - For default risk

## *Conclusion*

- Two different models have been investigated
- Contagion homogeneous Markovian models
  - Perfect hedge of default risks
  - Easy implementation
  - Poor dynamics of credit spreads
  - No individual name effects
- Multivariate Cox processes
  - Rich dynamics of credit spreads
  - But no contagion effects
  - Thus, default risk can be diversified at the index level
  - Replication of CDO tranches is feasible by hedging only credit spread risks.
