De Finetti theorem and factor representation

• Homogeneity assumption: default indicators D_1, \ldots, D_n forms an exchangeable Bernoulli random vector

Definition (Exchangeability)

A random vector (D_1, \ldots, D_n) is exchangeable if its distribution function is invariant for every permutations of its coordinates: $\forall \sigma \in S_n$

$$(D_1,\ldots,D_n)\stackrel{d}{=}(D_{\sigma(1)},\ldots,D_{\sigma(n)})$$

Same marginals

De Finetti theorem and factor representation

- Assume that D_1, \ldots, D_n, \ldots is an exchangeable sequence of Bernoulli random variables
- ullet Thanks to de Finetti's theorem, there exists a unique random factor $ilde{
 ho}$ such that
- ullet D_1,\ldots,D_n are conditionally independent given $ilde{p}$
- Denote by $F_{\tilde{p}}$ the distribution function of \tilde{p} , then:

$$P(D_1 = d_1, ..., D_n = d_n) = \int_0^1 p^{\sum_i d_i} (1-p)^{n-\sum_i d_i} F_{\tilde{p}}(dp)$$

 \bullet \tilde{p} is characterized by:

$$\frac{1}{n}\sum_{i=1}^{n}D_{i}\stackrel{a.s}{\longrightarrow}\tilde{p} \text{ as } n\to\infty$$

• \tilde{p} is exactly the loss of the infinitely granular portfolio (Basel 2 terminology)

Stochastic orders

- The convex order compares the dispersion level of two random variables
- Convex order: $X \leq_{cx} Y$ if $E[f(X)] \leq E[f(Y)]$ for all convex functions f
- Stop-loss order: $X \leq_{sl} Y$ if $E[(X K)^+] \leq E[(Y K)^+]$ for all $K \in \mathbb{R}$
 - $X \leq_{sl} Y$ and $E[X] = E[Y] \Leftrightarrow X \leq_{cx} Y$

Supermodular order

- The supermodular order captures the dependence level among coordinates of a random vector
- $(X_1, ..., X_n) \leq_{sm} (Y_1, ..., Y_n)$ if $E[f(X_1, ..., X_n)] \leq E[f(Y_1, ..., Y_n)]$ for all supermodular functions f

Definition (Supermodular function)

A function $f: \mathbb{R}^n \to \mathbb{R}$ is supermodular if for all $x \in \mathbb{R}^n$, 1 < i < j < n and $\varepsilon, \delta > 0$ holds

$$f(x_1,\ldots,x_i+\varepsilon,\ldots,x_j+\delta,\ldots,x_n)-f(x_1,\ldots,x_i+\varepsilon,\ldots,x_j,\ldots,x_n)$$

$$\geq f(x_1,\ldots,x_i,\ldots,x_j+\delta,\ldots,x_n)-f(x_1,\ldots,x_i,\ldots,x_j,\ldots,x_n)$$

Müller(1997)

Stop-loss order for portfolios of dependent risks

$$(D_1,\ldots,D_n)\leq_{sm}(D_1^*,\ldots,D_n^*)\Rightarrow\sum_{i=1}^nM_iD_i\leq_{sl}\sum_{i=1}^nM_iD_i^*$$

Main results

- Let us compare two credit portfolios with aggregate loss $L_t = \sum_{i=1}^n M_i D_i$ and $L_t^* = \sum_{i=1}^n M_i D_i^*$
- Let D_1, \ldots, D_n be exchangeable Bernoulli random variables associated with the mixing probability \tilde{p}
- Let D_1^*, \ldots, D_n^* exchangeable Bernoulli random variables associated with the mixing probability \tilde{p}^*

Theorem

$$\tilde{p} \leq_{cx} \tilde{p}^* \Rightarrow (D_1, \ldots, D_n) \leq_{sm} (D_1^*, \ldots, D_n^*)$$

- In particular, if $\tilde{p} \leq_{cx} \tilde{p}^*$, then:
 - $E[(L_t a)^+] < E[(L_t^* a)^+]$ for all a > 0.
 - $\rho(L_t) \leq \rho(L_t^*)$ for all convex risk measures ρ

Main results

- Let D_1, \ldots, D_n, \ldots be exchangeable Bernoulli random variables associated with the mixing probability \tilde{p}
- Let $D_1^*, \ldots, D_n^*, \ldots$ be exchangeable Bernoulli random variables associated with the mixing probability \tilde{p}^*

Theorem (reverse implication)

$$(D_1,\ldots,D_n) \leq_{sm} (D_1^*,\ldots,D_n^*), \forall n \in \mathbb{N} \Rightarrow \tilde{p} \leq_{cx} \tilde{p}^*.$$

Ordering of CDO tranche premiums

- Analysis of the dependence structure in several popular CDO pricing models
- An increase of the dependence parameter leads to:
 - a decrease of [0%, b] equity tranche premiums (which guaranties the uniqueness of the market base correlation)
 - an increase of [a, 100%] senior tranche premiums

Additive factor copula approaches

- The dependence structure of default times is described by some latent variables V_1, \ldots, V_n such that:
- $V_i = \rho V + \sqrt{1 \rho^2} \, \bar{V}_i, \ i = 1 \dots n$
- $V, \bar{V}_i, i = 1 \dots n$ independent
- $\tau_i = G^{-1}(H_{\rho}(V_i)), i = 1 \dots n$
 - ullet G: distribution function of au_i
 - H_{ρ} : distribution function of V_i
- ullet $D_i=1_{\{ au_i\leq t\}},\;i=1\ldots n$ are conditionally independent given V
- $\frac{1}{n}\sum_{i=1}^{n}D_{i} \stackrel{a.s}{\longrightarrow} E[D_{i} \mid V] = P(\tau_{i} \leq t \mid V) = \tilde{p}$

Additive factor copula approaches

Theorem

For any fixed time horizon t, denote by $D_i=1_{\{\tau_i\leq t\}},\ i=1\dots$ n and $D_i^*=1_{\{\tau_i^*\leq t\}},\ i=1\dots$ n the default indicators corresponding to (resp.) ρ and ρ^* , then:

$$\rho \leq \rho^* \Rightarrow \tilde{p} \leq_{\mathsf{cx}} \tilde{p}^* \Rightarrow (D_1, \dots, D_n) \leq_{\mathsf{sm}} (D_1^*, \dots, D_n^*)$$

- This framework includes popular factor copula models:
 - One factor Gaussian copula the industry standard for the pricing of CDO tranches
 - Double t: Hull and White(2004)
 - NIG, double NIG: Guegan and Houdain(2005), Kalemanova, Schmid and Werner(2007)
 - Double Variance Gamma: Moosbrucker(2006)

Archimedean copula

Schönbucher and Schubert (2001), Gregory and Laurent (2003), Madan et al. (2004), Friend and Rogge (2005)

- ullet V is a positive random variable with Laplace transform $arphi^{-1}$
- U_1, \ldots, U_n are independent Uniform random variables independent of V
- $V_i = \varphi^{-1} \left(-\frac{\ln U_i}{V} \right), \ i = 1 \dots n \text{ (Marshall and Olkin (1988))}$
 - ullet (V_1,\ldots,V_n) follows a arphi-archimedean copula
 - $P(V_1 \leq v_1, \ldots, V_n \leq v_n) = \varphi^{-1}(\varphi(v_1) + \ldots + \varphi(v_n))$
- $\tau_i = G^{-1}(V_i)$
 - G: distribution function of τ_i
- $D_i = 1_{\{\tau_i \leq t\}}, i = 1 \dots n$ independent knowing V
- $\frac{1}{n} \sum_{i=1}^{n} D_i \xrightarrow{a.s} E[D_i \mid V] = P(\tau_i \leq t \mid V)$

Archimedean copula

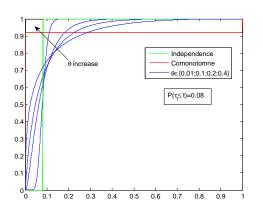

• Conditional default probability: $\tilde{p} = \exp\{-\varphi(G(t)V)\}$

Copula	Generator $arphi$	Parameter
Clayton	$t^{- heta}-1$	$ heta \geq 0$
Gumbel	$(-\ln(t))^{ heta}$	$ heta \geq 1$
Franck	$-\ln\left[(1-e^{- heta t})/(1-e^{- heta}) ight]$	$ heta \in I\!\!R^*$

Theorem

$$\theta \leq \theta^* \Rightarrow \tilde{p} \leq_{cx} \tilde{p}^* \Rightarrow (D_1, \dots, D_n) \leq_{sm} (D_1^*, \dots, D_n^*)$$

Archimedean copula

- Clayton copula
- Mixture distributions are ordered with respect to the convex oder

Structural model

Hull, Predescu and White(2005)

- Consider n firms
- Let $V_{i,t}$, $i = 1 \dots n$ be their asset dynamics

$$V_{i,t} = \rho V_t + \sqrt{1 - \rho^2} \bar{V}_{i,t}, \quad i = 1 \dots n$$

- V, \bar{V}_i , $i=1\ldots n$ are independent standard Wiener processes
- Default times as first passage times:

$$\tau_i = \inf\{t \in \mathbb{R}^+ | V_{i,t} \leq f(t)\}, i = 1 \dots n, f : \mathbb{R} \to \mathbb{R} \text{ continuous}$$

• $D_i = 1_{\{\tau_i \leq T\}}$, $i = 1 \dots n$ are conditionally independent given $\sigma(V_t, t \in [0, T])$

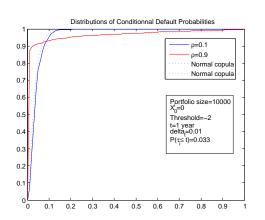

Structural model

Theorem

For any fixed time horizon T, denote by $D_i=1_{\{\tau_i\leq T\}},\ i=1\dots n$ and $D_i^*=1_{\{\tau_i^*\leq T\}},\ i=1\dots n$ the default indicators corresponding to (resp.) ρ and ρ^* , then:

$$\rho \leq \rho^* \Rightarrow (D_1, \dots, D_n) \leq_{sm} (D_1^*, \dots, D_n^*)$$

Structural model

•
$$\frac{1}{n} \sum_{i=1}^{n} D_i \xrightarrow{a.s} \tilde{p}$$

$$\bullet \quad \frac{1}{n} \sum_{i=1}^{n} D_{i}^{*} \xrightarrow{a.s} \tilde{p}^{*}$$

• Empirically, mixture probabilities are ordered with respect to the convex order: $\tilde{p} \leq_{cx} \tilde{p}^*$

Duffie(1998), Lindskog and McNeil(2003), Elouerkhaoui(2006)

- ullet $ar{N_t^i}$ Poisson with parameter $ar{\lambda}$: idiosyncratic risk
- N_t Poisson with parameter λ : systematic risk
- $(B_i^i)_{i,j}$ Bernoulli random variable with parameter p
- All sources of risk are independent

•
$$N_t^i = \bar{N}_t^i + \sum_{j=1}^{N_t} B_j^i, i = 1 \dots n$$

•
$$\tau_i = \inf\{t > 0 | N_t^i > 0\}, i = 1 \dots n$$

- Dependence structure of (τ_1, \ldots, τ_n) is the Marshall-Olkin copula
- $\tau_i \sim Exp(\bar{\lambda} + p\lambda)$
- ullet $D_i=1_{\{ au_i\leq t\}},\;i=1\dots n$ are conditionally independent given N_t
- $\bullet \ \ \frac{1}{n} \sum_{i=1}^{n} D_{i} \xrightarrow{a.s} E[D_{i} \mid N_{t}] = P(\tau_{i} \leq t \mid N_{t})$
- Conditional default probability:

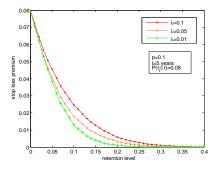

$$ilde{p} = 1 - (1-p)^{N_{oldsymbol{t}}} \exp(-ar{\lambda}t)$$

- Comparison of two multivariate Poisson models with parameter sets $(\bar{\lambda}, \lambda, \rho)$ and $(\bar{\lambda}^*, \lambda^*, \rho^*)$
- Supermodular order comparison requires equality of marginals: $\bar{\lambda} + p\lambda = \bar{\lambda}^* + p^*\lambda^*$
- 3 comparison directions:
 - $p = p^*$: $\bar{\lambda}$ v.s λ
 - $\lambda = \lambda^*$: $\bar{\lambda}$ v.s p
 - $\bar{\lambda} = \bar{\lambda}^*$: λ v.s p

Theorem $(p = p^*)$

Let parameter sets $(\bar{\lambda}, \lambda, p)$ and $(\bar{\lambda}^*, \lambda^*, p^*)$ be such that $\bar{\lambda} + p\lambda = \bar{\lambda}^* + p\lambda^*$, then:

$$\lambda \leq \lambda^*, \ \bar{\lambda} \geq \bar{\lambda}^* \Rightarrow \tilde{p} \leq_{cx} \tilde{p}^* \Rightarrow (D_1, \dots, D_n) \leq_{sm} (D_1^*, \dots, D_n^*)$$

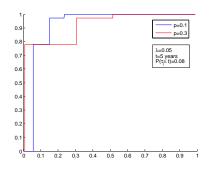

- Computation of $E[(L_t a)^+]$:
 - 30 names
 - $M_i = 1, i = 1 \dots n$
- When λ increases, the aggregate loss increases with respect to stop-loss order

Theorem $(\lambda = \lambda^*)$

Let parameter sets $(\bar{\lambda}, \lambda, p)$ and $(\bar{\lambda}^*, \lambda^*, p^*)$ be such that $\bar{\lambda} + p\lambda = \bar{\lambda}^* + p^*\lambda$, then:

$$p \leq p^*, \; \bar{\lambda} \geq \bar{\lambda}^* \Rightarrow \tilde{p} \leq_{cx} \tilde{p}^* \Rightarrow (D_1, \ldots, D_n) \leq_{sm} (D_1^*, \ldots, D_n^*)$$

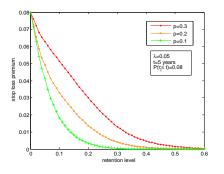

Convex order for mixture probabilities

Theorem $(\lambda = \lambda^*)$

Let parameter sets $(\bar{\lambda}, \lambda, p)$ and $(\bar{\lambda}^*, \lambda^*, p^*)$ be such that $\bar{\lambda} + p\lambda = \bar{\lambda}^* + p^*\lambda$, then:

$$p \leq p^*, \ \bar{\lambda} \geq \bar{\lambda}^* \Rightarrow \tilde{p} \leq_{cx} \tilde{p}^* \Rightarrow (D_1, \dots, D_n) \leq_{sm} (D_1^*, \dots, D_n^*)$$

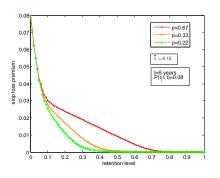

- Computation of $E[(L_t K)^+]$:
 - 30 names
 - $M_i = 1, i = 1 \dots n$
- When p increases, the aggregate loss increases with respect to stop-loss order

Theorem $(\bar{\lambda} = \bar{\lambda}^*)$

Let parameter sets $(\bar{\lambda}, \lambda, p)$ and $(\bar{\lambda}^*, \lambda^*, p^*)$ be such that $p\lambda = p^*\lambda^*$, then:

$$p \leq p^*, \ \lambda \geq \lambda^* \Rightarrow \tilde{p} \leq_{cx} \tilde{p}^* \Rightarrow (D_1, \dots, D_n) \leq_{sm} (D_1^*, \dots, D_n^*)$$

- Computation of $E[(L_t K)^+]$:
 - 30 names
 - $M_i = 1, i = 1 \dots n$
- When p increases, the aggregate loss increases with respect to stop-loss order

Conclusion

- When considering an exchangeable vector of default indicators, the conditional independence assumption is not restrictive thanks to de Finetti's theorem
- The mixing probability (the factor) can be viewed as the loss of an infinitely granular portfolio
- We completely characterize the supermodular order between exchangeable default indicator vectors in term of the convex ordering of corresponding mixing probabilities
- We show that the mixing probability is the key input to study the impact of dependence on CDO tranche premiums
- Comparison analysis can be performed with the same method within a large class of CDO pricing models

Exchangeability: how realistic is a homogeneous assumption?

- Homogeneity of default marginals is an issue when considering the pricing and hedging of CDO tranches
 - ex: Sudden surge of GMAC spreads in the CDX index in May, 2005
 - This event dramatically impacts the equity tranche compared to the others
- But composition of standard indices are updated every semester, resulting in an increase of portfolio homogeneity
- It may be reasonable to split a credit portfolio in several homogeneous sub-portfolios (by economic sectors for example)
 - Then, for each sub-portfolio, we can find a specific factor and apply the previous comparison analysis
 - The initial credit portfolio can thus be associated with a vector of factors (one by sector)
 - Is it possible to relate comparison between global aggregate losses to comparison between vectors of random factors?

Are comparisons in a static framework restrictive?

- Are comparisons among aggregate losses at fixed horizons too restrictive?
- Computation of CDO tranche premiums only requires marginal loss distributions at several horizons
 - Comparison among aggregate losses at different dates is sufficient
- However, comparison of more complex products such as options on tranche or forward started CDOs are not possible in this framework
- Building a framework in which one can compare directly aggregate loss processes is a subject of future research
